PROCESSING AND PROPERTY INDEX

THEORY OF THE TINNING PROCESS. I. Fesiosenko- Czopiwski and J. Strzalko (Prz. Corn.-Hutn., 1930, 22, 379-382). The fact that the solubility of C in Fe increases with increasing amounts of Sn in solid solution in the Fe is significant when Fe is tinned at too high temp.: optimal temp. are 260-300°, an uneven layer of Sn being produced at higher temp. owing to corrosion, probably because Fe diffuses into Sn more rapidly than the reverse action takes place. The hardness of the Fe near the Sn layer increased from 125 to 162 kg. per sq. mm., whilst that of the Sn near the Fe increased from 6 to 86 kg. per sq. mm.

SIRZALKOWSKA (HALINA). *Egullisna wodnista Pomidora*. [Watery rot of the Tomato.]—*Acta Soc. Bot. Polonica*, vii, 4, pp. 599-614, 1930. [French summary. Received May, 1932.]

This is a brief account of a watery rot which in 1928 and 1929 was frequently found destroying tomatoes in the markets of Warsaw. It is distinct from similar rots reported from other countries [the characters of which are briefly described], in that the lesions apparently start at any point of the surface of the fruits, presumably through microscopical ruptures in the cuticle, since inoculation tests showed that the causal organism is unable to penetrate the uninjured skin. The infection gradually spreads until the whole fruit is reduced to a semi-transparent liquid mass with a peculiar acid (but not putrid) smell. Besides numerous yeast-like organisms (which were shown to be non-pathogenic), isolations from the rotting tomatoes yielded a short (1-12 by 0.75 μ), non-motile, non-sporulating, Gram-negative rod, usually occurring in pairs but sometimes isolated and occasionally disposed in short

AS 53.5.4 METALLURGICAL LITERATURE CLASSIFICATION

chains. It grew best on tomato juice agar and on carrot, on which it formed rounded, mucous, yellowish-white colonies with a glistening surface. Cultural studies (details of which are given) showed that the organism develops better on solid than in liquid media; it does not liquefy gelatine or coagulate milk, and cannot utilize starch; of nitrogenous substances it can only utilize proteins and peptone, the latter only in the presence of sugar. Its temperature range for growth is from 3° to 37° C., with an optimum between 22° and 26°. It is considered to be new to science and the name *Bacterium lycopersici citiati* K. Bassalik et H. Strzalkowaka is suggested for it. A brief Latin diagnosis is appended. Typical

watery rot was produced in healthy tomatoes inoculated with pure cultures of the bacterium, which was reisolated from the infected fruits.

Title : Experiments in Utilization of Coli Phages to Counteract
Development of Intestinal Bacteria in Cheese.

Orig Pub : Prace Inst. przem. mleczarsk., 1956, 3, No 2-9, 19-25.

Abstract : From samples of milk and cheese with indications of early bulging, 130 strains of intestinal bacilli were isolated belonging to *Escherichia coli*, intermediate groups and *Aerobacter aerogenes*. Coli phages which dissolved these strains were isolated from bulging cheeses, milk, drainage waters, feces of suckling infants, cows, wild mammals, and birds. The activity of phage mixtures was increased somewhat by multiple passages through sensitive and resistant strains on liquid and solid media, as well as by washings with a 1% peptone water from

AUTHOR: Strzelba, H., Doctor

TITLE: Universal paints on the basis of reaction varnishes

PERIODICAL: Plaste und Kautschuk, v. 8, no. 3, 1961, 164 - 167

TEXT: Studies were made to develop reaction varnishes with long storage stability, good stability against the effects of weather, chemicals and temperatures between - 30° and + 50°C, and which might be used on timber and metal. Since polyurethane varnish raw materials are not produced in Eastern Germany, epoxy resins hardened with amines were used. The epoxy resin Epilox EG 1 of the VEB Leuna-Werke "Walter Ulbricht" (State-owned Leuna Plant "Walter Ulbricht") was used, which, according to its properties, is classified between Shell-Epikote 900 and 1001. Since basic zinc chromate and zinc oxide retard complete hardening, iron oxide, strontium and barium chromate, potassium-barium chromate, chromium oxide, metal powder applied to silica gel which retarded, however, complete hardening, zinc tetraoxy-chromate and zinc chromate were used as pigments, ethylene glycol

Universal paints on the basis of ...

toluol (or xylol) 1:1 als solvents, and as amine component mainly diethylene triamine, the adduct from 21 g of diethylene triamine on 100 g of Epilox EG 1 (in butanol-toluol 1:1) and polyamides (Versamid 100, 115, and 125). When triethylene triamine is used, exact maintaining of the stoichiometric amounts by weight of the reactants is necessary; the content of epoxy groupings of the resin must be determined, e.g., according to Bring and Kadlecek by cleavage of the epoxy groups with the aid of pyridine perchlorate (see Plaste und Kautschuk, v. 5 (1958) no. 2, 43-48) or according to Buser (Leuna) by means of a pyridine hydrochloride solution. Besides, in this case the resin-hardener mixture must react in advance for 6 hr before it may be used. The length of time during which the varnish may be used after mixing the components, amounts to about one day when diethylene triamine is used, and 2 to 3 days when using polyamides. This time is shorter at higher temperatures (20 hr at 20°C, 8 hr only at 30°C); no cross-linking reaction takes place below 10°C. The use of methyl-ethyl ketone as solvent lengthened the time, while an excess of hardener reduced it. An admixture of 4% Aerosil from the firm of Degussa or of Kirusol from the VEB Farbenfabrik Wolfen (State-owned Dye Plant Wolfen)

Card 2/5

prevents settling of the varnish. The following compositions are mentioned as examples: for red-brown: 33-34% iron oxide red; 66-67% of 50% solution of Epilox EG1, and as hardener 10 parts of a mixture of 17.9% diethylene triamine and 82.1% solvent; for light gray: 48% Rutil, a trace of gas-black, 35% of 50% solution of Epilox EG1, 9% ethylene glycol, 8% xylene, and as hardener 10 parts of a mixture of 9.4% diethylene triamine and 90.6% solvent (ethylene-glycol-xylene 1:1 was used). When applied by spraying, the varnish surface sometimes showed defects which could be prevented by the use of other solvents, such as methyl-ethyl ketone. The varnish could be applied without difficulties by brushing and dipping. A wash-primer 5692/1005 from the VEB Dye and Varnish Plant Leipzig was used for priming, as well as a self-prepared epoxy ester primer and one prepared by the Weissensee Research Center. These last two primers had to be stored at 80°C in order to prevent wrinkling when applying epoxy varnish. Coats of paint made in this way were tested for resistance against chemicals, the amount of hardener, advance reaction time and several days of storage of the paints not impairing the stability, in contrast to several publications. Only solvents containing chlorine have a de-

X

Universal paints on the basis of ...

destructive effect; a destruction of the coat of paint by all other common chemicals, which partly took place after a duration of action of from 9 to 18 days, could be prevented by suitable hardeners. Further tests will permit classification of the hardeners according to their corrosion-preventing effect. An impact strength of below 10 cm/180 g, a pendulum hardness according to König of about 166 s, and adhesion values according to Brichsen of 1.4 and 2.7 mm are mentioned as characteristic mechanical strength values for reaction varnishes after complete hardening. The effect of weather as well as a test for six and a half weeks (55 hr ultraviolet light, .32 hr immersion in water, 84 hr 100% air humidity at 40°C and 2 hr SO₂ fume) caused the coats of paint to grow dull and chalky; a test cycle (six and a half weeks) of 24 hr at -20°C, and of 24 hr at +50°C caused no damage. The coats of paint are only inflammable under direct action of a flame, the storage stability of the individual varnish components amounts to at least 12 months, and the varnish has a better resistance to abrasion than nitrocellulose varnish or that stored at 80°C. The tests are not yet finished. The practical applicability of the varnishes developed is not discussed. The article is the shortened version of a lecture delivered at

Strzelbicki, J. Single Pipeline System for Pumping Crude Oil and Natural Gas from the Well to the Storage Tank.

Jednorurociagowy system przetlaczania ropy i gazu ziemnego z odwiertu do zbiornika magazynowego. Nafta. No. 2, 1953, pp. 39-42, 5 figs.

The closed system of oil production increases the total output by preventing losses in light hydrocarbons. The author recommends a modification which improves the existing system of closed exploitation. He describes the technical and operative features of the modified type of equipment. This new system considerably simplifies the handling of equipment and centralises crude oil and natural gas management, besides enabling, as the result of a more accurate determination of the gas production exponent, closer control to be exercised over the exploitation of petroleum reservoirs.

(1) fuel
157. Single pipe system for pumping crude oil and natural gas from the well to the storage tank. J. T. Stzelbicki. *Nafta (Kutno)*, 1953, 9, 39-42. Totally enclosed exploitation equipment prevents loss of light hydrocarbons which generally reach 5%. Certain difficulties in construction of such equipment are now overcome by author's invention (Polish Patents P 35171 and P 35101). Instead of separating crude oil and natural gas at well and leading them to separate tanks, both are taken into one tank (gas), from which lower layer (oil) is then removed. Gas is then transferred to another tank, where natural gasoline is removed by compressing it to 5 atm.

"Tracheotomy in Severe Cases of Tetanus"

Warsaw, Polski Tygodnik Lekarski, Vol XVIII, No 7, 11 Feb
1963, pp 241-244

Abstract: /Authors' English summary modified/ The results of
treatment of patients with tetanus achieved in the Clinic
of Infectious Diseases in 1960 and 1961 are reported. Among
62 patients 47 recovered, 15 died. Tracheotomy was performed
in the 12 most severe cases. In all patients signs usually
predicting exitus appeared. 7 were saved. Tracheotomy perfor-
med early, proper doses of chlorpromazine and thiopental in-
fusion and good "tetanus nursing" are the best way of treat-
ing severe cases of tetanus. 3 tables; 15 references, half
of them Western.

TITLE: Polymerization conditions and molecular weight distribution of polystyrene

SOURCE: Plaste und Kautschuk, no. 1, 1966, 4-8

TOPIC TAGS: dimerization, polymerization accelerator, polymerization inhibitor, polystyrene, molecular weight, peroxide, emulsion polymerization

ABSTRACT: The article reports on the results of an experimental investigation to obtain preliminary information on the problem of determining what deviation from standard polymerization parameters produces the variations in the parameters of the polystyrenes produced commercially. To this end every effort was made to fabricate a given and definite type of polystyrene under fixed and given polymerization conditions. The molecular weight distribution of polystyrene, prepared by peroxide initiated emulsion polymerization, was determined and it was found that of all the polymerization conditions, the only changes in the initial heating rate and the

Card 1/2

ACC NR:AF6018459

concentration of active oxygen in the initiator, and the properties of certain polystyrene indicated in text have been investigated. The dependence of molecular weight distribution on polymerization conditions is discussed, and data is given on the workability of polystyrene. It is announced that research on the problem is continuing and that more reports will be forthcoming. Orig. art. has: 10 figures, 7 formulas and 2 tables.

1631. Results and interpretation of experimental geochemical studies. K. Strzelecki. *Prace Instytutu Naftowego*, 1955, Series A, No. 46, p. 20. — Geochemical investigations are intended to discover light hydrocarbons in the surface of the earth and to relate their presence to oil reservoirs. 2 "complex" geochemical profiles have been described in the paper, one of a recognized oil-bearing area of Potok and the other of a region between Lodz and Nida basins, the so-called "Przedbor Bridge," which overlays a Jurassic anticline. Here oil can only be suspected, and the geochemical work, although supporting such a hypothesis, needs further support of more orthodox methods. M. S.
